Description

Semiconductor Device and Manufacturing Method Thereof

add line
numbering

Technical Field

This invention relates to a semiconductor device containing a dielectric capacitor and a manufacturing method thereof; and, more ^{particularly} ^{the invention} in particular, it relates to a semiconductor device in which an electrode comprising Ru, RuO₂ or a mixed material of Ru and RuO₂ is deposited homogeneously on a substrate with a three-dimensional structure, and a manufacturing ^{of manufacture} method thereof.

Background Art of the Invention

Semiconductor memories include ^a DRAM (Dynamic Random Access Memory) ^{which is capable of} having a feature in high speed data rewriting. Along with progress in ultra large ^{scale} scaling integration technology, ^{the} DRAM has entered a large ^{capacity range} capacitance of 256 M^{to} 1 G bit. Therefore, ^{there has been a demand for} integration has been demanded for ^{of} circuits; and, ^{more} ^{the} particularly, ^{effectively} size of capacitors for storing information has been made finer. Means for ^{in the} the integration of capacitors can include reduction (of) film thickness of dielectrics, selection of materials of high dielectric constant and a three-dimensional structure comprising top and bottom electrodes and a dielectric.

these choices

Among, ~~them~~, for the dielectric material, it has been known that BST having a single unit cell of perovskite structure ((Ba/Sr)TiO₃) as the crystal structure has ^a higher dielectric constant (ϵ) compared with SiO₂/Si₃N₄. An example of using high dielectric materials has been reported in Japan Journal of Applied Physics, 1995, 5077p (Jpn. J. Appl. Phys., 34, 5077, 1995). According to this report, since the condition for the aspect ratio (contact hole patterns of 800nm depth/240nm diameter) of ~~the~~ ^a three-dimensional structure using BST is about 0.65, top and bottom electrodes and a dielectric are prepared by a sputtering method.

Summary *the*
[Disclosure] of ^{the} Invention

In the prior art described above, since Pt or Ru of the bottom electrode is prepared by the sputtering method, ~~(it)~~ ^{there is} ~~(involves)~~ a problem ⁱⁿ that the three-dimensional structure shows poor step coverage, and adhesion to the inside wall is small compared with that to the surface and the bottom, so that a highly three-dimensional device structure with an aspect ratio of ^{one} [1] or more can not be attained.

This invention has been accomplished to overcome the foregoing problems and ^{has the object of providing} ~~(intends to provide)~~ a semiconductor device, including a dielectric capacitor having excellent step coverage in a device structure at ^a high aspect ratio, along with

[the trend of]^a high integration [degree], as well as a
[manufacturing] method^{of manufacture} thereof.

Heretofore, although there has been a report of
preparing^{an} electrode comprising Ru, RuO₂ or a mixture of Ru and
RuO₂ thin films by a sputtering method on a three-dimensional
structure with a small aspect ratio, [but] a film forming
technique^{using a} [by an] metalorganic chemical vapor deposition process
(MOCVD) has not been taken into consideration.

The present inventors have found that a homogeneous
electrode comprising Ru, RuO₂ or a mixture of Ru and RuO₂ thin
films can be prepared on^a substrate having a three-dimensional
structure within a temperature range from 180°C or higher to
250°C or lower by an MOCVD process using a cyclopentadienyl
complex. The principle^{which makes it possible to prepare} [capable of preparing] a homogeneous
film in the temperature range described above [is to] ^{will} be
^{with reference to Fig 5} explained [below].

Fig. 5 shows a crystal structure of a ruthenium
cyclopentadienyl complex used in^{accordance with} this invention. δ or π bonds
are present between a 5 cyclic and ruthenium metal, and a
temperature at 180°C or higher is necessary as the energy of
dissociation in view of^{the} bonding energy. Further, the adhesion
rate of the complex is constant on^a Si substrate within a
temperature range from 180°C or higher and 250°C or lower, and
decomposition - adhesion on the surface proceeds

preferentially at a higher temperature.

Accordingly, a film is formed only on the surface (top plane of protruded portions) in a substrate having a three-dimensional structure to form inhomogeneous films with the film thickness reduced on the inside wall and the bottom (top plane of convex portions). Particularly at a temperature higher than 300°C, island crystals are formed due to ^arapid decomposing reaction to form ^arough film quality for which contact can not be attained. Accordingly, a homogeneous electrode comprising Ru, RuO₂ or a mixture of Ru and RuO₂ thin films can be formed ^{on} [to] the surface, the bottom and the inside wall on a substrate having a three-dimensional structure by the MOCVD process using a ruthenium cyclopentadienyl complex within a temperature range from 180°C or higher to 250°C or lower.

Further, the present inventors have found that ^a [a] ^{an} electrode comprising Ru, RuO₂ or a mixture of Ru and RuO₂ thin films can be formed homogeneously by the MOCVD process using a β-diketone complex within a temperature range from 300°C or higher to 500°C or lower when a structure having a three-dimensional ^{configuration} is constituted of two insulation layers, namely, a surface layer with ^asmall adhesion rate and a inside wall layer with ^alarge adhesion rate. The principle ^{will} [is to] be explained ^{with reference to Fig 2} [below].

Fig. 2 shows a crystal structure of a ruthenium β -diketone complex used in^{accordance with} this invention. π bonds are present between oxygen in a 6 cyclic and ruthenium metal and can dissociate at a temperature of 300°C or higher in view of the bond energy. However, since dissociation of^{an} oxygen - carbon bond or dissociation of^{an} oxygen - ruthenium bond proceeds simultaneously, the adhesion rate is small and decomposition - deposition near the surface proceeds preferentially. Further, at a temperature higher than 500°C, island crystals are formed due to violent decomposing reaction to result in^a film quality^{that is} not capable of attaining contact. Then, as shown in Fig. 3, a homogeneous electrode thin film comprising Ru, RuO₂ or a mixture of Ru and RuO₂ can be prepared ^{on} [to] the surface, the bottom and the inside wall within a temperature range from 300°C or higher to 500°C or lower by an MOCVD process using a ruthenium β -diketone complex on^a structure having a three-dimensional^{configuration} by constituting the structure having a three-dimensional^{configuration} with an insulation layer^{consisting} of a dual layered structure comprising a surface layer 31 having a small adhesion rate and a side wall layer 32 having a large adhesion rate, for example, MgO/SiO₂ or Al₂O₃/SiO₂ for the electrode material.

This invention has been accomplished based on the

studies as described above, and it [has a feature ^{features} in] a method of manufacturing a semiconductor device [of] ^{by} laminating to form a bottom electrode, a dielectric and a top electrode on a substrate having a three-dimensional structure, wherein a bottom electrode and a top electrode are formed by a metalorganic chemical vapor deposition method at a temperature of 180°C or higher and 250°C or lower using a cyclopentadienyl complex as ^a precursor.

The cyclopentadienyl complex is used as an Ru precursor and, ^{more} particularly, dicyclopentadienyl ruthenium is preferred. The bottom electrode and the top electrode are formed each as a thin film comprising Ru, RuO₂ or mixture of Ru and RuO₂.

By using one of O₂, H₂, N₂O, O₃, CO and CO₂ as a reaction gas, ^a decomposing reaction from the precursor can be promoted to form a film at a low temperature of 180°C or higher to 250°C or lower. Particularly, in a gas mixture of a reaction gas and a carrier gas (Ar, He or N₂ gas), the ratio of the reaction gas to the carrier gas is preferably 1% or more.

According to this feature, an electrode thin film can be prepared homogeneously [to] ^{on} the surface, the bottom and the side wall on the substrate having a three-dimensional structure. Accordingly, it is possible to obtain a dielectric capacitor of high integration degree comprising a top electrode/a dielectric/a bottom electrode having a three-

dimensional structure of high aspect ratio of 3 or more (contact hole depth/diameter).

Further, this invention ^{features} (has a feature in) a method of manufacturing a semiconductor device ^{by} (of) laminating to form a bottom electrode, a dielectric and a top electrode on a substrate having a three-dimensional structure, wherein the (structure having a) ^{structure is} three-dimensional, constituted of an ^{consisting} insulation film of a two-layered structure comprising a surface layer with a small adhesion rate and a side wall layer with a large adhesion rate for the starting electrode material, and the bottom electrode and the top electrode are formed by ^A metalorganic chemical vapor deposition process using a β -diketone complex as the precursor at a temperature of 300°C or higher and 500°C or lower.

The β -diketone complex is used as the precursor for Ru and dibivaloylmethanate ruthenium is particularly preferred. The bottom electrode and the top electrode are formed each as a thin film comprising Ru, RuO₂, or a mixture of Ru and RuO₂.

A decomposing reaction is promoted at a temperature of 300°C or higher to 500°C or less to prepare a homogeneous electrode thin film by using one of O₂, H₂, N₂O, O₃, CO and CO₂ as the reaction gas while using one of Ar, He and N₂ as the carrier gas. In the gas mixture of the reaction gas to the carrier gas, the ratio of the reaction gas and the carrier gas

may be 0% or more. That is, the reaction gas may or may not be used.

According to this feature, since the [structure having a] ^{structure} three-dimensional, is constituted of two insulation layers comprising a surface layer of small adhesion rate and a side wall layer of large adhesion rate, and the electrode thin film can also be formed on the side wall to which it is less vapor deposited, an electrode thin film of uniform film thickness comprising Ru, RuO₂ or a mixture of Ru and RuO₂ can be prepared. Accordingly, [it can provide] ^{can be provided which includes} a semiconductor device [including] a dielectric capacitor ^{with} [of] a device structure having a high aspect ratio of 3 or more, corresponding to ^a [the] high integration degree, and having a step coverage performance. Particularly, when the structure comprising two insulation layers is MgO/SiO₂ or Al₂O₃/SiO₂, a uniform electrode thin film can be prepared depending on the different adhesion rate of the precursor.

Further, this invention ^{features} [has a feature in] a semiconductor device having a dielectric and electrodes for applying a voltage to the dielectric in which the electrode is a thin film electrode comprising Ru, RuO₂ or a mixture of Ru and RuO₂ formed on a structure with an aspect ratio of the three-dimensional structure (contact hole depth/diameter) of 3 or more.

The semiconductor device can contain an electrode thin

film of a uniform thickness comprising a Ru, RuO₂ or a mixture of Ru and RuO₂ manufactured by an MOCVD process from a cyclopentadienyl complex, or an electrode thin film of a uniform thickness comprising Ru, RuO₂ or a mixture of Ru and RuO₂ manufactured by an MOCVD process from the β -diketone complex of high integration degree having a top electrode/[a] dielectric/[a] bottom electrode. Since the electrode thin film is formed homogeneously ^{on} [a] the surface, the bottom and the side wall on the substrate having a three-dimensional ^{structure}, it is possible to obtain a dielectric capacitor of high integration degree ^{which is} [and] capable of functioning intactly having a three-dimensional structure of high aspect ratio. When such a dielectric capacitor is used for semiconductor devices, such as ^a DRAM, the capacity can be increased.

Further, this invention has a feature of forming the bottom electrode and the top electrode by a metalorganic chemical vapor deposition process of liquid carrying and evaporation using a starting solution in which a precursor containing a cyclopentadienyl complex is dissolved in tetrahydrofuran, toluene, hexane or octane. According to this feature, since the precursor can be supplied stably for a long period of time, a bottom electrode and a top electrode with good film quality can be formed and a semiconductor device with high performance can be manufactured. The

^{of manufacture of}
 [manufacturing] method [for] the semiconductor device according to
^{for use}
 this invention is excellent, in [the] mass [productivity]^{production} of [the]
 semiconductor devices. In the manufacturing method [of the]
[^]
 [semiconductor device] according to this invention, a bottom
 electrode and a top electrode, which are homogeneous and [with] [^]
 high quality, can be formed at a temperature of 180°C or higher
 and 250°C or lower.

Further, this invention has a feature of forming the
 bottom electrode and the top electrode by a metalorganic
 chemical vapor deposition process of liquid carrying and
 evaporation using a starting solution in which a precursor
 containing a β -diketone complex is dissolved in
 tetrahydrofuran, toluene, hexane or octane. According to
 this feature, since the precursor can be supplied stably for a
 long period of time, a bottom electrode and a top electrode
 with good film quality can be formed and a semiconductor
 device with high performance can be manufactured. The
^{producing}
 manufacturing method for the semiconductor device according to
^{for use}
 this invention is excellent, in [the] mass [productivity]^{production} of [the]
 semiconductor devices. In the manufacturing method [of the]
[^]
 [semiconductor device] according to this invention, a bottom
 electrode and a top electrode which are homogeneous and [with] [^]
 high quality can be formed at a temperature of 300°C or higher
 and 500°C or lower.

When the liquid carrying and evaporation metalorganic chemical vapor deposition process using a starting solution in which a precursor containing the cyclopentadienyl complex or the β -diketone complex is dissolved in a tetrahydrofuran solvent is used, since the starting solution can be stored at [a] room temperature, thermal denaturation of the precursor as ^{typically} caused ^{when using} [in] the sublimation method can be suppressed, and, as a result, the precursor can be supplied stably for a long period of time. The liquid carrying and evaporation metalorganic chemical vapor deposition process is a method ^{correctly} of dissolving a precursor into a solvent to prepare a starting solution, heating the starting solution in an evaporator to obtain an evaporated precursor and conducting the chemical vapor deposition process.

Further, this invention has a feature ^{of} [in] using a solvent having a solubility of 0.05 mol/l or more for the precursor, such as tetrahydrofuran, toluene, hexane or octane. According to this feature, since evaporation of the precursor and the solvent ^{takes} [is taken] place simultaneously in the evaporation step of the liquid carrying and evaporation metalorganic chemical vapor deposition process, the precursor can be supplied stably for a long period of time ^{which makes it possible} to manufacture a semiconductor device with ^a higher performance.

In a case of a solvent with a solubility of 0.05 mol/l

or lower, only the solvent of lower boiling point is evaporated selectively in an evaporator; and, as a result, the precursor of high boiling point is deposited in the inside of the evaporator to cause clogging, making it difficult to provide a stable (stably) supply. The solubility of the diethylcyclopentadienyl ruthenium ($\text{Ru}(\text{EtCp})_2$) complex as the cyclopentadienyl complex to each kind of (the) solvent is 1.74 mol/l for tetrahydrofuran, 1.4 mol/l for toluene, 1.4 mol/l for hexane and 1.4 mol/l for octane, and the precursor can be supplied stably in the liquid carrying and evaporation metalorganic chemical vapor deposition process. Further, the solubility of the dibivaloylmethanate ruthenium ($\text{Ru}(\text{dpm})_3$) complex as the β -diketone complex [is] to each kind of the solvent is 0.52 mol/l for tetrahydrofuran, 0.45 mol/l for toluene, 0.27 mol/l for hexane and 0.25 mol/l for octane, and the starting material can be supplied stably in the liquid carrying and evaporation metalorganic chemical vapor deposition process.

Further, in accordance with this invention, since the organic ingredient of the precursor and the reaction gas ^{are subjected to} (take place) combustion or reductive reaction in the course of forming the film when O_2 , H_2 , CO or CO_2 is used as the reaction gas, the residual carbon content in the electrode film for the bottom electrode and the top electrode can be defined ^{as} 10^{-2} at% or more and 1 at% of less, by which ^a high quality bottom electrode

and top electrode not causing contact failure can be formed, and a semiconductor device with high performance can be manufactured.

Further, this invention ^{features} [has a feature in] a method of forming a thin film ^{on} [to] the surface and the lateral side of a structure having a three-dimensional ^{shape} in which the structure comprises ^{the} [in] ^{of} lamination, a two layered structure ^{connecting} of a surface layer with ^a small adhesion rate and a side wall layer with a large adhesion rate for the starting thin film material. Use of the 2-layered structure ^{described with reference to} [explained in] Fig. 3 is not restricted only to the case of forming the Ru thin film as the electrode by the MOCVD process and is generally applicable also in ^a [the] film forming method, such as a sputtering method, a vacuum vapor deposition method or an MBE method as a method for forming a homogeneous film ^{on} [to] the surface, the side wall and the bottom in a case where the film tends to be deposited preferentially only ^{on} [to] the surface.

Best Mode for Carrying Out the Invention

A method of manufacturing a semiconductor device according to this invention ^{will} ~~is to~~ be explained specifically with reference to the drawings.

[Example 1]

A method of manufacturing a semiconductor device using a crystal structure shown in Fig. 5 of a discyclopentadienyl ruthenium (RuCp_2) complex in which $\text{R} = \text{H}$ ^{will be described} ~~is shown below~~. ^PFig. 4 is a cross sectional view of a dielectric capacitor

contained in a semiconductor device manufactured in, this example. ^{accordance with}

At first, an Si wafer 41 was heated to 300°C and a contact hole is opened in an SiO₂ layer 44 formed by thermal oxidation, and then an Si plug 42 is prepared. Then, a barrier layer 43 made of a TiN layer of 100 Å thickness was prepared on the Si plug 42 by a sputtering method. Further, after forming an SiO₂ layer 45 of 8000 Å thickness by a plasma CVD process using starting TEOS material, a 2400 Å diameter was fabricated around the contact hole as a center to prepare a substrate having a three-dimensional ^{shape}. The aspect ratio (contact hole depth/diameter) of the three-dimensional structure is 3.33.

A bottom electrode 46 was prepared on the substrate. For the preparation of the bottom electrode 46, an RuCp₂ complex was formulated at a concentration of 0.05 to 0.25 mol/l into a THF (tetrahydrofuran) solvent to form a CVD precursor. The CVD precursor was supplied at a rate of 0.1 to 3 sccm by using a liquid mass flow controller. After converting the CVD precursor all at once from liquid to gas by setting the temperature of a vaporizer to 80 to 150°C, it was carried on an Ar gas at 198 to 500 sccm. Then, after mixing the CVD/Ar gas with oxygen gas at 2 to 800 sccm, they were introduced into a reactor. The pressure in the reactor was

set to 0.01 to 50 torr, the film forming temperature was set to 180°C or higher and 250°C or lower to form film for 1 to 20 min to obtain a film thickness of 20 to 30 nm.

As a result of measurement by X-ray diffractiometry for the obtained film, it was found to be an Ru film at 1 to 25%, an Ru/RuO₂ mixed film at 25 to 50% and an RuO₂ film at 50 to 400%. Further, the film is in the form of RuO₂ even if the O₂/Ar ratio is 400% or more. By the way, in a case where O₂/Ar = 0%, granular crystals were formed to provide ^{an}inhomogeneous film quality.

Fig. 1 shows cross sectional SEM images of the Ru film obtained at the O₂/Ar ratio of 5%. It was found that the Ru film was formed homogeneously ^{on}[to] the surface, the bottom and the side wall, and the film has a step coverage (film side wall/film surface) of 100%. Further, the surface roughness of the film was ± 10 Å or less and the film quality was extremely smooth. As a result of measurement for ^a[the] specific resistivity, the resistance was as low as $\rho = 50 \mu\Omega/\text{cm}^2$ at [a] room temperature.

Further, when the residual amount of carbon was analyzed along the direction of the depth in the film by secondary ion mass spectroscopy, the carbon content was within a range from 10^{-2} at% or more to 1 at% or less, and it was a thin film with high quality.

Then, $(\text{Ba}, \text{Sr})\text{TiO}_3(\text{BST})$ was prepared as a dielectric 47 on the bottom electrode 46 by an MOCVD process. Barium dibivaloylmethanate $\text{Ba}(\text{dpm})_2$, $\text{Sr}(\text{dpm})_2$ and $\text{Ti}(\text{O}-i\text{-Pr})_2(\text{dpm})_2$ were used for the precursors and each of the materials was prepared at a concentration of 0.05 to 0.25 mol/l into a THF solvent to form a CVD precursor. Each of the CVD precursor was supplied at a rate of 0.1 to 3 sccm from a liquid mass flow controller to an evaporator set to 250°C . The CVD precursor gas was introduced by the Ar carrier gas at 200 sccm into the reactor and 5 to 100 sccm of an oxygen gas was also introduced to the reactor. Film adhesion was conducted for 3 min by setting the pressure of the reactor to 0.01 to 50 torr and a film forming temperature to 420°C , to form a BST thin film to 30 nm.

Then, the film was heat treated at 700°C for 30 to 60 sec in an N_2 or Ar gas to improve the crystallinity. A top electrode 48 was formed on the dielectric 47. The film was formed by the same method and under the same conditions as those for forming the bottom electrode 46, to obtain a homogeneous thin Ru film with 100% step coverage on the three-dimensional ^{structure} with an aspect ratio of 6.17. The thus obtained dielectric capacitor showed excellent electrical characteristics with the specific dielectric constant ε [at 1 V] ^{at 1V} of 300.

In addition to the discyclopentadienyl ruthenium complex in which $R = H$, homogeneous thin Ru films could be formed as the bottom electrode and the top electrode by the same method as described above also in a case of using dis(methylcyclopentadienyl) ruthenium at $R = CH_3$, dis(ethylcyclopentadienyl) ruthenium at $R = C_2H_5$, dis(propylcyclopentadienyl) ruthenium at $R = C_3H_7$, dis(butylcyclopentadienyl) ruthenium at $R = C_4H_9$.

Further, while O_2 was used as the reaction gas, as described above, a homogeneous thin Ru film could be formed also by using one of H_2 , N_2O , O_3 , CO and CO_2 . Further, while the Ar gas has been explained as the carrier gas, an He or N_2 gas may also be used, and it has been found that any combination of them can form an Ru film at 1 to 25%, an Ru/RuO₂ mixed film at 25 to 50% and an RuO₂ film at 50 to 400% or more as the reaction gas to the carrier gas ratio.

[Example 2]

A method of manufacturing a semiconductor device using a crystal structure of β -diketone complex shown in Fig. 2 of a dibivaloylmethanate ruthenium ($Ru(dpm)_3$) complex in which $R' = C(CH_3)_3$ ^{will be described} [is shown] below. ^P Fig. 6 is a cross sectional view of a dielectric capacitor contained in a semiconductor device ^{accordance with} manufactured in this example.

 In the same manner as in Example 1, after opening a contact hole to an SiO₂ layer 64 formed by thermally oxidizing an Si wafer 61, preparing an Si plug 62 and then forming a TiN barrier layer 63, an insulation layer 65 of an SiO₂ layer was prepared to a thickness of 7800 Å by a plasma CVD process. Then, an MgO layer was deposited as an insulation layer 66 by a sputtering process using Mg as a target. A film of 200 Å thickness was obtained by using a 1:1 gas mixture of oxygen and argon as a sputtering gas at a film forming pressure of 2 Pa and with RF power of 200 W. A 2400 Å diameter was fabricated around a contact hole as a center to prepare a substrate having a three-dimensional structure. The aspect ratio of the three-dimensional structure is 3.33.

A bottom electrode 67 was prepared on the substrate. For the preparation of the bottom electrode 67, dibivaloylmethanate ruthenium (Ru(dpm)₃) of the crystal structure of the β-diketone complex at R' = C(CH₃)₃ shown in Fig. 2 was formulated at a concentration of 0.05 to 0.25 mol/l in a THF solvent to form a CVD precursor. The CVD precursor was supplied at a rate of 0.1 to 3 sccm by using a liquid mass flow controller. After converting the CVD precursor all at once from liquid to gas by setting the temperature for the evaporator to 100 to 200°C, it was carried on an Ar gas at 198 to 500 sccm. Then, after mixing the CVD/Ar gas and an oxygen

gas at 0 to 800 sccm, they were introduced into a reactor. A film of 20 to 30 nm thickness was obtained by depositing a film at a pressure of the reactor of 0.01 to 50 torr, at a film forming temperature of 300°C or higher to 500°C or lower for 1 to 20 min.

As a result of measurement by X-ray diffractiometry for the obtained film, it has been found that the film is an Ru film at 0 to 25% or less, an Ru/RuO₂ mixed film at 25 to 50% or less and an RuO₂ film at 50 to 400% or more as O₂/Ar ratio. From the result of SEM observation for the cross section of the Ru film of 20 nm thickness obtained at the O₂/Ar ratio of 0%, it has been found that the Ru film was formed homogeneously ^{on} (to) the surface, the bottom and the side wall, and the step coverage of the film (film side wall/film surface) was about 100%. Further, the surface roughness of the film was $\pm 8 \text{ \AA}$ or less, ^{an} showing extremely smooth film quality. As a result of measurement for the specific resistivity, the resistance was as low as $\rho = 50 \text{ } \mu\Omega/\text{cm}^2$ at (a) room temperature.

Then, BST was prepared to a film thickness of 30 nm as a dielectric 68 on the bottom electrode 67 by an MOCVD process in the same manner as in Example 1. Then, a heat treatment was applied in an N₂ or Ar gas at 700°C for 30 to 60 sec, to improve the crystallinity. A top electrode 69 was formed on the dielectric 68. The top electrode 69 was formed by forming

a film by the same method and under the same conditions as those in the formation of the bottom electrode 67 and a homogeneous thin Ru film with 100% step coverage could be formed on the aspect ratio of 6.17. The thus obtained dielectric capacitor showed excellent electrical characteristics with the specific dielectric constant ϵ of 300 at 1 V.

An identical homogeneous thin Ru film could also be prepared by using an Al_2O_3 layer manufactured by a sputtering process using Al as a target, instead of MgO as an insulation layer 66.

Homogeneous Ru thin films could be formed on the bottom electrode and the top electrode by the same method as described above also in a case of using acetylacetonate ruthenium at $\text{R} = \text{CH}_3$ and hexafluoroacetyl acetate ruthenium at $\text{R} = \text{CF}_3$ in addition to the dibivaloylmethanate ruthenium complex at $\text{R} = \text{C}(\text{CH}_3)_3$.

Further, while O_2 was used as the reaction gas, a homogeneous Ru thin film could be formed also by using one of H_2 , N_2O , O_3 , CO and CO_2 . Further, while^a description has been made^d to the^{use of} Ar gas as the carrier gas, [an] He or N_2 gas may also be used, and it has been found that any combination of them could form an Ru film at a ratio of 0 to 25%, an Ru/ RuO_2 mixed film at 25 to 50% and an RuO_2 film at 50 to 400% or more

as the reaction gas to the carrier gas ratio.

[Example 3]

A third example of this invention ^{will} [is to] be explained with reference to Fig. 7. ^{RP} Fig. 7 is a cross sectional view of a dielectric capacitor contained in a semiconductor device ^{according with} manufactured in this example.

In the same manner as in Example 1, after opening a contact hole to an SiO₂ layer 74 formed by thermally oxidizing an Si wafer 71, preparing an Si plug 72 and then forming a TiN barrier layer 73, an Ru layer was formed by a sputtering process using Ru as a target. A film of 5000 Å thickness was obtained by using an Ar gas as a sputtering gas, at a film forming pressure of 2 Pa and with an RF power of 1200 W. Then, a top electrode 75 having a three-dimensional ^{structure} was formed by fabricating a trapezoidal shape around the contact hole as a center. The aspect ratio of the three-dimensional structure is 3.0.

Then, BST as a dielectric 76 was formed to ^a 30 nm film thickness on the bottom electrode 75 by an MOCVD process in the same method as in Example 1. Then, ^a heat treatment was applied in an N₂ or Ar gas at 700°C for 30 to 60 sec to improve the crystallinity. A top electrode 77 was formed on the dielectric 76. The top electrode 77 was formed by preparing a

thin film of Ru, RuO₂ or a mixture of Ru and RuO₂ at a thickness of 20 nm under the same conditions as those in Example 1 by a CVD process using ^aRuCp₂/THF precursor. The resultant dielectric capacitor showed excellent electrical characteristics with a specific dielectric constant ϵ of $\boxed{1 \text{ V}}$ ^{at 1V} $\boxed{\text{at}} 280\%$.

[Example 4]

A fourth example of this invention ^{will} [is to] be explained with reference to Fig. 8. ^aFig. 8 is a cross sectional view of ^aDRAM as a semiconductor device using the dielectric capacitor prepared in Example 1.

Device isolation oxide films 83a, 83b were prepared by an oxidizing method on a P-type semiconductor substrate 81, and N-type source/drain regions 80a, 80b, 80c were prepared on the main surface of the semiconductor substrate by ion implantation. Gate electrodes 81a, 82b, 82c and 82d each of 200 nm film thickness were formed by way of a gate oxide film of 12 nm thickness on a channel region. A buried bit line 84 connected electrically was formed on the source/drain region 80b by photolithography and dry etching, and an SiO₂ layer 14 was formed so as to cover the entire surface. Subsequently, a dielectric capacitor comprising a top electrode, a dielectric and a bottom electrode was prepared by the method shown in

Example 1. Then, after forming an interlayer insulation film 88 so as to cover the top electrode 19, the film was flattened by a chemical etching method. First layer aluminum wirings were formed at a space thereon, an insulation protective film 86 was prepared so as to cover the wirings and a second layer aluminum wiring layers 87 were formed thereon. In the same manner as described above, ^aDRAM can be prepared also by using the dielectric capacitor prepared in Example 2.

While the THF solvent was used in the MOCVD process for forming the top electrode and the bottom electrode in Examples 1 to 4, there is no particular restriction for the solvent so long as it is a material capable of dissolving the precursor, and toluene or ether may be used, for example, with no trouble.

Furthermore, the method of forming the top electrode and the bottom electrode ^{as} explained in Examples 1 to 4 is the MOCVD process starting from a starting precursor, but similar effects could also be obtained by a material gas supply method by a sublimation method from a solid precursor or a starting gas supply method by a bubbling method from a liquid precursor. Particularly, since the precursor can be supplied stably for a long period of time by forming the bottom electrode and the top electrode by a liquid carrying and evaporation metalorganic chemical vapor deposition method, the bottom electrode and the top electrode with good film quality can be

^{so as} formed, ^{produce} to (manufacture) a semiconductor device with high performance.

(Industrial Applicability)

According to this invention, a semiconductor device containing a dielectric capacitor having an excellent step coverage for a device structure ^{having} [of] a high aspect ratio corresponding to ^a high degree of integration can be obtained.

Abstract of the Disclosure

A semiconductor device containing a dielectric capacitor having an excellent step coverage for a device structure of high aspect ratio corresponding to high integration degree, as well as a manufacturing method therefor, are provided. A dielectric capacitor of high integration degree is manufactured by forming a bottom electrode 46 and a top electrode 48 comprising a homogeneous thin Ru film with 100% step coverage while putting a dielectric 47 therebetween on substrates 44, 45 having a three-dimensional structure with an aspect ratio of 3 or more by a MOCVD process using a cyclopentadienyl complex within a temperature range from 180°C or higher to 250°C or lower.
